

Sick dataset analysis

Tomasz Makowski

17 04 2020

Introduction

The object of this analyse is to predict if person is sick or not. First, we can see the basic introduction of dataset.

```
introduce(data = dataset_raw)
```

```
##   rows columns discrete_columns continuous_columns all_missing_columns
## 1 3772     30           23             6             1
##   total_missing_values complete_rows total_observations memory_usage
## 1             6064             0             113160             577048
```

```
plot_missing(dataset_raw)
```

There is one column with all missing values so we can remove this column and see more information about dataset without this column. Few columns have missing values. We should drop those columns, drop proper rows or impute data.

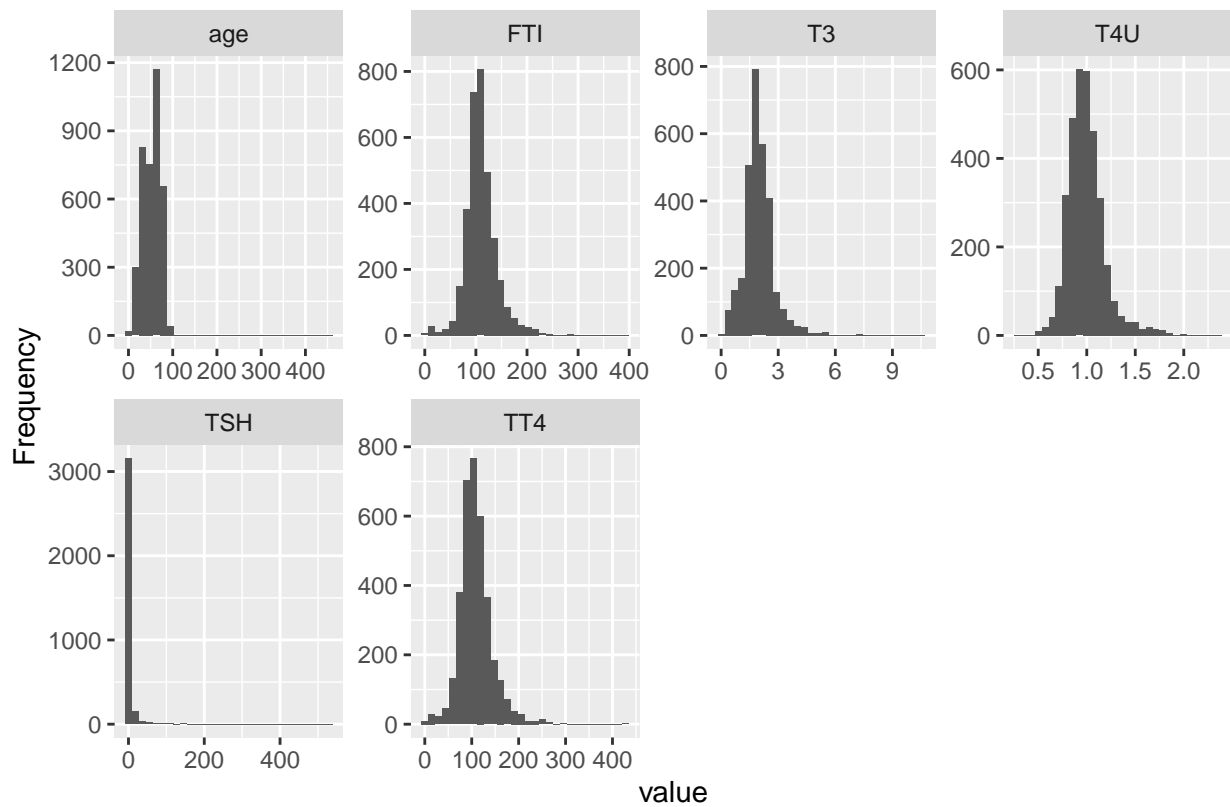

```
dataset <- dataset_raw %>%
  # drop 'TBG' and 'TBG_measured' - it is an empty column
  select(-c(TBG, TBG_measured))
plot_intro(dataset)
```

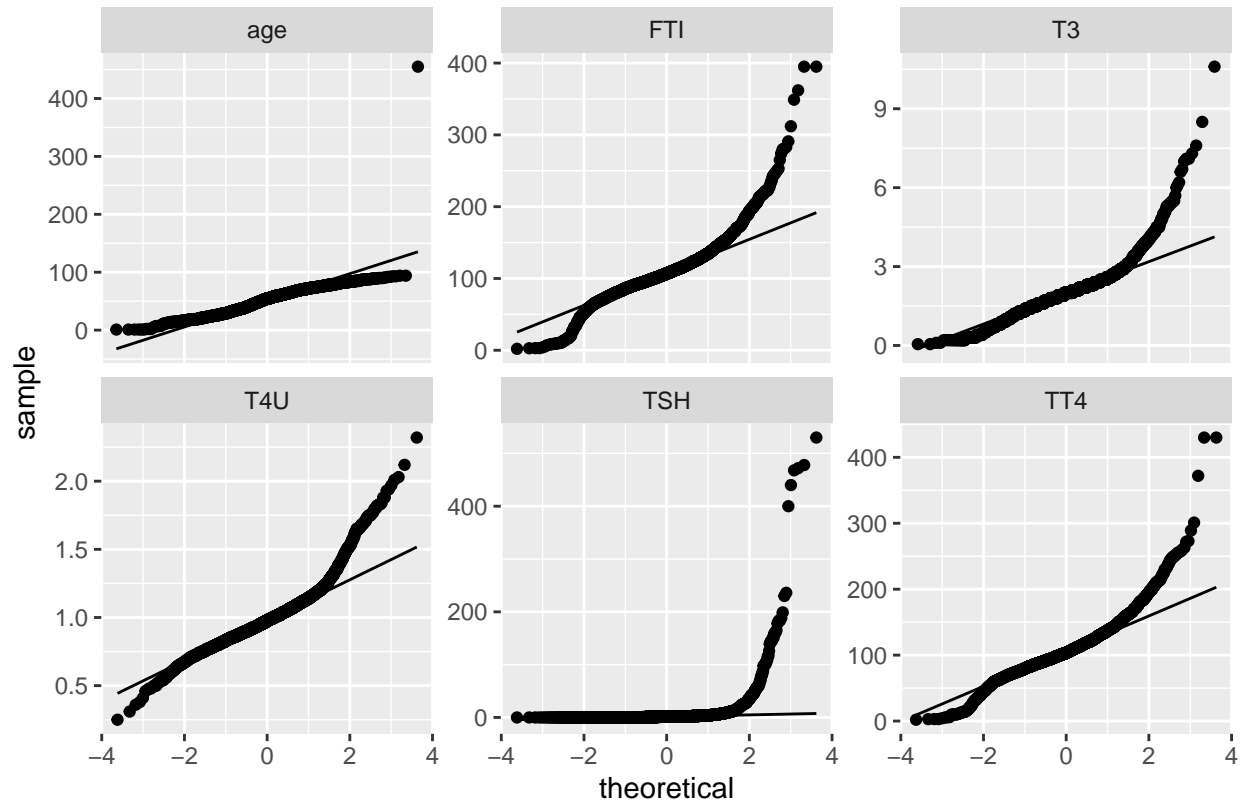

As

we can see missing data are usually in the same rows. So dropping all columns is a bad idea.

```
plot_correlation(dataset)
```

```
plot_qq(dataset)
```

```
plot_boxplot(dataset, by="Class")
```

There are some values that should be removed - especially age around 400. Also in TSH, FTI and TT4 we can try to remove few outliers and replace them as the mean value. Also it could be good to change TSH by applying logarithm since there are many values near 0 and outliers are only bigger than 0.

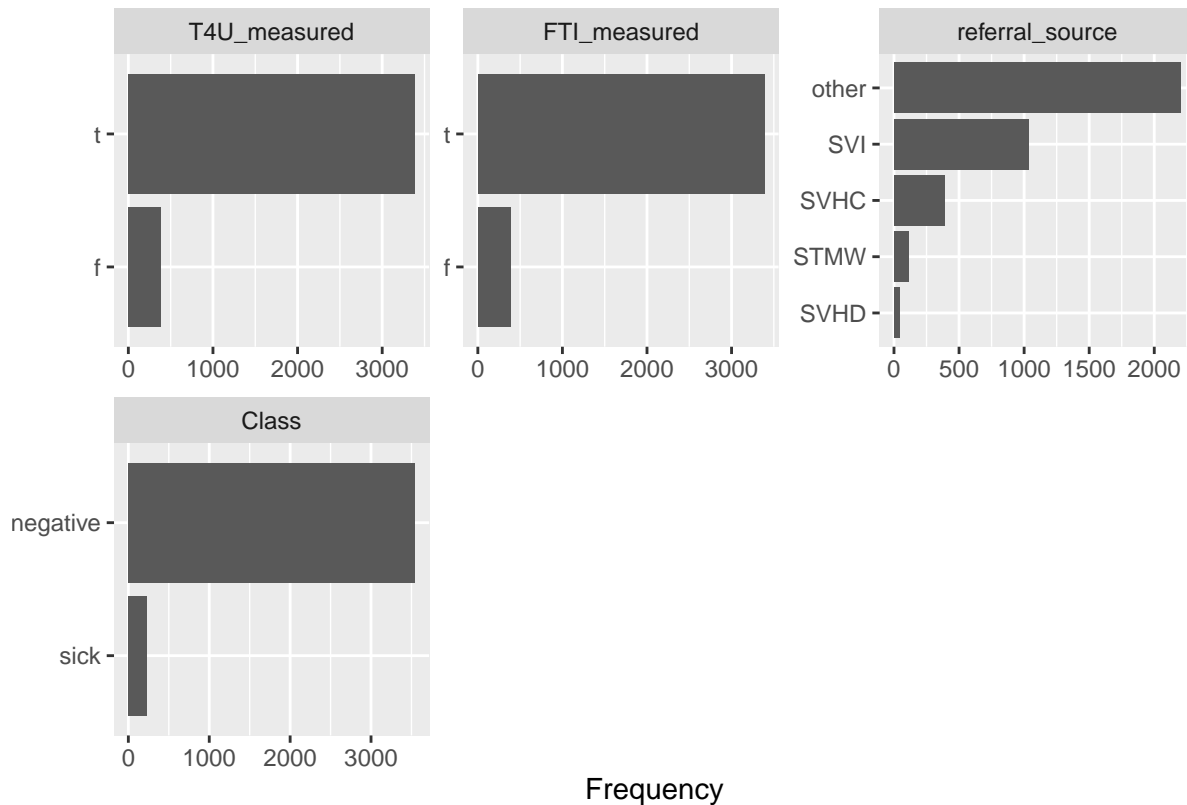

```
plot_bar(dataset)
```

Page 1

Page 2

Page 3

There are some columns with only few observation with one of the categories. Below are their number of occurrence and how much it tell about sick class.

```
sum(dataset_raw$hypopituitary == "t")
```

```
## [1] 1
```

```
sum(dataset_raw$lithium == "t")
```

```
## [1] 18
```

```
sum(dataset_raw$goitre == "t")
```

```
## [1] 34
```

```
sum(dataset_raw$on_antithyroid_medication == "t")
```

```
## [1] 43
```

```
sum(dataset_raw$thyroid_surgery == "t")
```

```
## [1] 53
```

```
sum(dataset_raw$referral_source == "SVHD")
```

```
## [1] 39
```

```
sum(dataset_raw[dataset_raw$lithium == "t", "Class"] == "sick")
```

```
## [1] 1
```

```
sum(dataset_raw[dataset_raw$goitre == "t", "Class"] == "sick")
```

```
## [1] 2
sum(dataset_raw[dataset_raw$on_antithyroid_medication == "t", "Class"] == "sick")

## [1] 0
sum(dataset_raw[dataset_raw$thyroid_surgery == "t", "Class"] == "sick")

## [1] 0
sum(dataset_raw[dataset_raw$referral_source == "SVHD", "Class"] == "sick")

## [1] 3
```

Based on additional data it can be good to remove hypopituitary, lithium, goitre, on_antithyroid_medication and thyroid_surgery columns because there are up to 53 occurrences and only up to 2 sick people so those columns do not give any additional information but some algorithms can have problems with training models.

Preprocessing

Because of first look for data we can remove values with probable mistakes during writing, then we can remove hypopituitary column. After that we can one hot encode categorical data to use in algorithms.

```
# remove too big values - many written by mistake
dataset[dataset$age > 120 & (is.na(dataset$age) == FALSE), "age"] <- mean(dataset$age, na.rm = TRUE)
dataset[dataset$TT4 > 300 & (is.na(dataset$TT4) == FALSE), "TT4"] <- mean(dataset$TT4, na.rm = TRUE)
dataset[dataset$FTI > 250 & (is.na(dataset$FTI) == FALSE), "FTI"] <- mean(dataset$FTI, na.rm = TRUE)
dataset[dataset$TSH > 100 & (is.na(dataset$TSH) == FALSE), "TSH"] <- mean(dataset$TSH, na.rm = TRUE)

# drop column hypopituitary because there are very few values
dataset <- dataset %>%
  select(-c(hypopituitary, lithium, goitre, on_antithyroid_medication, thyroid_surgery))

# one_hot encoding
target <- dataset$Class
target <- data.frame(target = as.factor(as.numeric(target == "sick")))
observed <- select(dataset, -Class)
dummy <- dummyVars(" ~ .", observed)
data_ohe <- data.frame(predict(dummy, newdata = observed))
data_ohe <- data_ohe %>% select(-sex.M)
dataset <- cbind(target, data_ohe)
```

Then we can impute data. We will use mice package and we try to do it 5 times. The algorithm do it iteratively so in every time the imputed data will be different. Then we can check which imputation gives the best results.

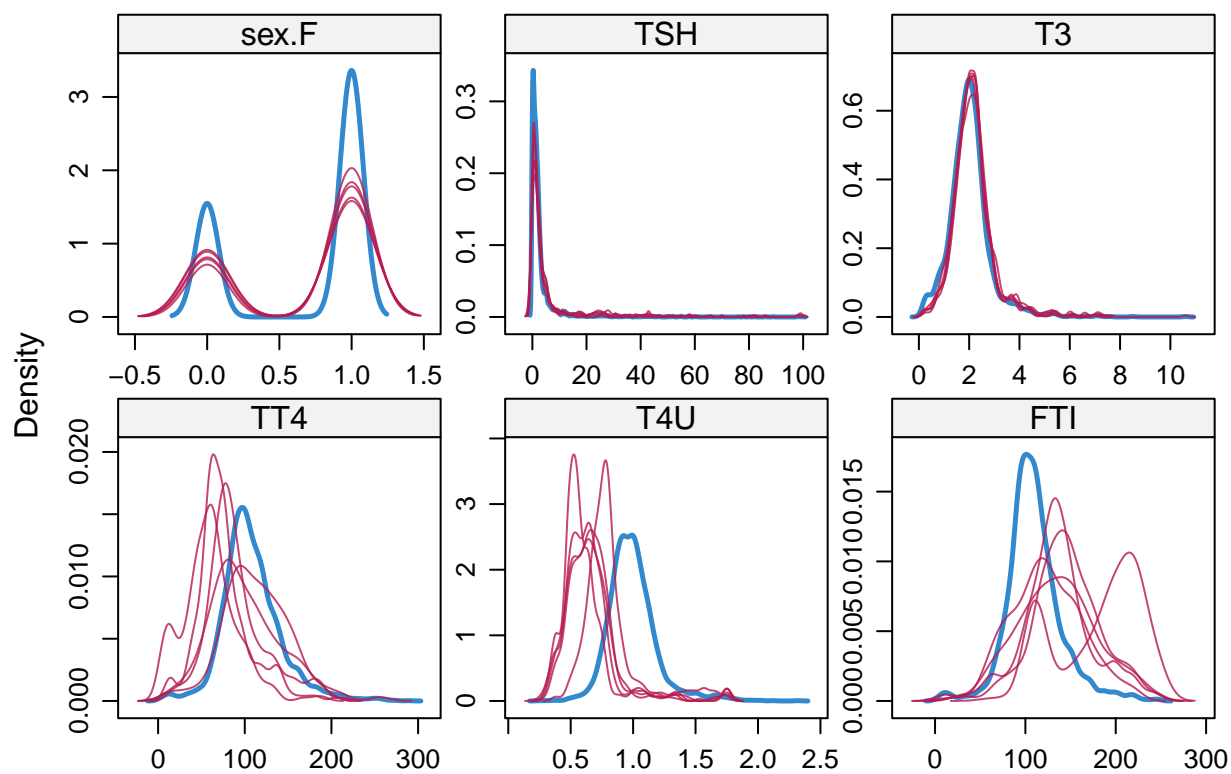

```
set.seed(1221)
mice_imputes <- mice(data_ohe, m=5, maxit = 10)
```

```
xyplot(mice_imputes, T4U~FTI | ifelse(sex.F==TRUE, "Female", "Male"), pch = 20, cex = 0.4)
```

```
densityplot(mice_imputes)
```

```

datasets <- list()
for(i in 1:5) {
  data <- complete(mice_imputes, i)
  data <- cbind(target, data)
  datasets[[i]] <- data
}

```

As we can see on density plots imputed data are good only for half of columns. TT4, T4U and FTI are not imputed well.

Model testing

Then we can test our model. We will test decision tree - rpart, logistic regression - log_reg, lda, glmnet, k nearest neighbours - kkn and naive bayes method - naive-bayes. We will try it on 12 prepared dataset in different ways. One dataset without anything, 5 datasets with data imputed by mice and two times more because in every dataset we will apply logarithm to TSH column.

The best model will be with the biggest AUPRC measure. It is good measure for imbalanced target classes. In our case there are less than 10% of sick people so AUPRC is better measure than AUC.

```

# 80% train i 20% test data
train_ind <- as.matrix(read.table("indeksy_treningowe.txt")[,2])
test_ind <- setdiff(seq_len(nrow(dataset)), train_ind)

# cross-validation
create_task_log <- function(dataset_log, id) {
  dataset_log$TSH <- log(dataset_log$TSH)
  task_log <- TaskClassif$new(id=id, backend=dataset_log[train_ind, ], target="target", positive="1")
  return(task_log)
}
task_base <- TaskClassif$new(id='basic', backend=dataset[train_ind, ], target="target", positive="1")
task_log <- create_task_log(dataset, 'TSH_logarithm')

imputed_tasks <- list()

##	task_id	learner_id	auc_test	auprc_test

The best algorithm is decision tree - rpart. So this algorithm will be used in final algorithm. The best result gives dataset without any changes. Maybe it is not worth to use imputed data because imputation has different density than basic dataset.

Final model

Below there are written results of final model on test dataset. Also there is a plot of precision recall curve of this model.

```
final_dataset <- dataset
final_dataset$TSH <- log(final_dataset$TSH)
task_final <- TaskClassif$new(id='imputed_data_best', backend=final_dataset, target="target", positive=

learner <- learners[[1]]
learner$train(task_final, row_ids=train_ind)
prediction <- learner$predict(task_final, row_ids=test_ind)
print(prediction$score(msr("classif.auprc")))
```

```
## classif.auprc
##      0.7701941
```

```
print(prediction$score(msr("classif.auc")))
```

```
## classif.auc
##      0.896633
```

```
auprc:precision_recall_curve(prediction$data$prob[, "1"], prediction$data$tab$truth, "1")
```
